

Solution Set 1

Posted: January 22

If you have not yet turned in the Problem Set, you should not consult these solutions.

1. We need to define a language that has the same computational power as the function f ; that is, given f one should be able to “easily” compute L_f , and vice versa. There are many ways to do this; here is one example:

Define

$$L_f = \{(x, k, b) : x \in \Sigma^*, b \in \Sigma, k \text{ an integer and the } k\text{-th symbol of } f(x) \text{ is } b\}.$$

The alphabet Γ thus includes Σ plus extra symbols to encode “(”, “)”, “,”, and integers (which can be written in binary, and thus encoded using two additional symbols).

To determine if a string z is in L_f using f , we first determine if z is of the form (x, k, b) . If it is, we evaluate $f(x)$, and accept iff the k -th symbol of $f(x)$ is b .

To compute $f(x)$ using L_f , we do the following: for $k = 1, 2, \dots$, we determine whether $(x, k, b) \in L_f$ for each $b \in \Sigma$, and we add the b for which we get a positive answer to the output. We stop when we reach a value of k for which $\forall b (x, k, b) \notin L_f$ (this marks the end of the string $f(x)$).

2. (a) This is an “if and only if” proof so it must be proven in both directions. That is, (1) given a regular language, show that it can be recognized by an all-paths-NFA, and (2) given an all-paths-NFA show that the language it recognizes is regular.
 - (1) If a language is regular, then by the equivalence theorems there is a FA that recognizes the language. Conveniently, a FA is an instance of an all-paths-NFA: since there is only one computation path for any given input, then strings are accepted only if all paths (the only path) ends in an accept state. So every regular language is recognized by an all-paths-NFA.
 - (2) To show that a language recognized by an all-paths-NFA is regular, we can construct a FA that recognizes the exact same language as a given all-paths-NFA. This can be done in the same way as the NFA-FA equivalence proof in the lecture slides (or Sipser, Theorem 1.39), with the following change: define the new machine’s accept states F' to be $\{R \in Q' \mid \text{every state in } R \text{ is an accept state of } M\}$. This corresponds to the fact that for the all-paths-NFA to accept a string, every computation on that string must end in an accept state.
- (b) If A and B are regular languages, then by part (a) there are all-paths-NFAs, M_a and M_b , that recognize each respectively. Given this fact, we can construct a third all-paths-NFA, M_c , that recognizes $C = (A \cap B)$. Simply create a start state with epsilon-transitions that point to the start states of M_a and M_b . A string is accepted by M_c if and only if all

computations end in accept states, which by the construction means all computations end in accept states in both M_a and M_b . Therefore M_c recognizes the intersection of A and B . By part (a) since C is recognized by an all-paths-NFA, it is a regular language.

- (c) L_{flip} is the complement of L . To see this, note that if x is a string in L , then some computation of M on x ends up in an accept state. Since accept states of M are not accept states in M_{flip} , and M_{flip} requires *all* computations to end in accept states, x cannot be a member of L_{flip} . On the other hand, if x is not a string in L , then all computations of M on x must end in reject states. Since reject states in M are accept states in M_{flip} , then all computations of x on M_{flip} end in accept states, and x is a member of L_{flip} .
3. Let L be the language consisting of all palindromes. Suppose L is a regular language. Then the Pumping Lemma must hold. Let p be the pumping length for L . Consider $w = \underbrace{aa \dots a}_p b \underbrace{aa \dots a}_p \in L$. Since $|w| \geq p$, w can be written as $w = xyz$ such that

- (a) for every $i \geq 0$, $xy^iz \in L$, and
 (b) $|y| > 0$, and
 (c) $|xy| \leq p$.

By (c), we see that $xy = aa \dots a$. Thus

$$xy^2z = \underbrace{aa \dots a}_{p+|y|} b \underbrace{aa \dots a}_p.$$

Since $|y| > 0$, xy^2z is not a palindrome, and thus it is not in L . Contradiction. We conclude that the language consisting of all palindromes is not regular.

4. (a) The easiest way to show that L_n is regular is to show a Finite Automaton A that accepts it. A will have n states S_0, S_1, \dots, S_{n-1} where the accept states are all the states except S_0 , which is the start state. The transition function is $\delta(S_j, 0) = S_{(j+1) \pmod n}$. In other words, the machine is in state s_j iff the number of symbols it has read so far, modulo n , is j .
- (b) Suppose PRIMES is a regular language. Then the Pumping Lemma must hold, so there is a pumping length p for this language. Let $q > p$ be a prime, and consider the string $w = \underbrace{00 \dots 0}_q$, which is in PRIMES.

By the Pumping Lemma, w can be written $w = xyz$, with $|y| = r > 0$, and for all $i \geq 0$, the string

$$xy^iz = \underbrace{00 \dots 0}_{q+(i-1)r}$$

is in PRIMES. This means that all the numbers $q + (i-1)r$ must be primes for all $i \geq 0$, but for $i = q+1$ we have $q + (i-1)r = q(1+r)$ with both q and $r+1 \geq 1$, which is a composite. Contradiction. We conclude that PRIMES is not a regular language.

5. This grammar generates the language L consisting of all strings with equal numbers of a 's and b 's.

We first prove that every x generated by the grammar is in L , by induction on the length of the derivation. For the base case, the only string that can be derived with a derivation of length 1 is ϵ , which is in L . Now consider a derivation $S \rightarrow aSb \rightarrow^* ayb$. By induction y is in L , and thus ayb is in L . A similar argument applies to each of the other two cases (i.e., the one in which the first step in the derivation is $S \rightarrow bSa$ and the one in which the first step in the derivation is $\rightarrow SS$).

We now prove that every $x \in L$ can be generated by the grammar. This is done by induction on the length of x . Let $x = st$, where s is the shortest prefix of x that is in L . Following the hint, we show that s cannot begin and end with the same character. To see this, define $f(i)$ to be the number of a 's minus the number of b 's in the prefix of x of length i . We have $f(0) = 0$, and $f(|s|) = 0$ (since $s \in L$). If s began and ended with a , then we would have $f(1) = 1$ and $f(|s| - 1) = -1$, which implies that there is some $1 < j < |s| - 1$ for which $f(j) = 0$, contradicting our assumption that s is the *shortest* prefix of x that lies in L . Similarly, if s began and ended with b , then we would have $f(1) = -1$ and $f(|s| - 1) = 1$, which implies that there is some $1 < j < |s| - 1$ for which $f(j) = 0$, contradicting our assumption that s is the shortest prefix of x that lies in L . We can therefore give a derivation of x that is either: $S \rightarrow SS \rightarrow aSbS \rightarrow^* st$ or $S \rightarrow SS \rightarrow bSaS \rightarrow^* st$, where the first S is used to derive s (which is possible by induction), and the second S is used to derive t (which again is possible by induction on the length of the string).
